🎯 Freelance Task: "Polish" the Design of 5 Pages (English)

Status	В процессе
Дедлайн	@March 17, 2026

Приоритет	P0

1. Overall Goal

There are 5 HTML pages (home, login, dashboard, analysis, journal). They already have a basic structure and classes. **They need to be made beautiful in a modern style (reference — solana.com), while preserving all logic and functionality.** You are NOT rewriting logic, NOT changing JS, NOT deleting content. You are only working with CSS and, if necessary, adding new classes to the HTML. The HTML files are a complete mess. They were created at different times, with no attention paid to aesthetics or proper structure. The closest one to having a structure that's actually starting to look decent is the analysis page. The rest are a disaster — you can't look at them without crying.

2. What Needs to Be Done

- Bring all 5 pages to a **unified style**.
- Use a **dark theme** (background — deep black/blue, like on solana.com).
- Make cards "glassmorphic" (`backdrop-filter: blur`), with thin borders.
- Make buttons, navigation, and input elements stylish, with smooth hovers.
- Add "air" (spacing between blocks).
- Typography: modern fonts (Inter, Outfit), large headings, good readability.

3. ⚠️ Strict Prohibitions (What NOT to Touch)

- **Do not change element IDs.** All `id="companyName"`, `id="priceChart"`, etc. must remain untouched (JS is attached to them).
- **Do not delete or rename existing classes** if they are used in JS. You can **add new classes**, but the old ones must stay.
- **Do not change the HTML structure** (order of tags, nesting) unless absolutely necessary. If you need to add a wrapper for styling — check with me first.
- **No React, Tailwind, or other frameworks.** We work only with pure HTML and CSS.
- **Do not touch the JS code** (all scripts are at the bottom of the page). I am responsible for their functionality.

4. Where and How to Make Changes

- **CSS:** You create one common CSS file (e.g., `redesign.css`), which is linked to all 5 pages. It should contain all the styles.
- **HTML:** You can **add new classes** to the markup for styling, but you cannot remove old ones. If you need to change the structure (e.g., wrap a block in a div for flex), be sure to ask me, and I'll take a look.

5. Reference and Examples

- Main reference: **solana.com** (dark theme, glass cards, thin borders, spacing).
- You can also look at **vercel.com**, **stripe.com** (their dark versions) — similar style.

6. List of Pages (4 pcs.)

1. `index.html` (home, public)
2. `login.html`
3. `dashboard.html` (user dashboard)
4. `stock-analysis.html` (ticker analysis)

5. `trading-journal.html` (trading journal)

7. Technical Requirements

- **Responsiveness:** Pages should look good on mobile (down to 375px) and tablets. Media queries are welcome.
- **Cross-browser compatibility:** Chrome, Firefox, Safari (latest versions).
- **Code cleanliness:** Comments in CSS are welcome, but the code should be readable and without clutter.
- **Fonts:** Use standard system fonts or import via Google Fonts (Inter, Outfit — I allow it).

8. Delivery and Interaction Process

I can send you by mail html's and css fails or through the platform

9. Payment

- We discuss a fixed price for all 5 pages.
- **Prepayment:** I don't do that. Payment upon completion and review.

10. Working with the Logo (Important Brand Feature)

I have an SVG logo embedded in the project. I want to have the ability to **flexibly control its colors via CSS** (for example, for seasonal themes: winter — blue shades, summer — green/gold shades, and also to highlight the diamond). Currently, the logo is connected via `#pp-logo` and `logo.css`, but the coloring works unreliably (colors are hardcoded or not stylable).

🔧 What Needs to Be Done:

1. **Convert the current logo embedding method to inline-SVG.** That is, instead of connecting via `<img>` or `background-image`, insert the SVG code directly into the HTML (in the header of each page). This will allow you to control its elements via CSS.
2. **Divide the logo into logical parts**, assigning them classes:

- For example, give the diamond icon a class `.logo-icon`, and the text part (the inscription "ProfitPal") — a class `.logo-text`.
- Inside the SVG itself, place these classes on the corresponding groups or paths.

3. **Color control via CSS variables:**
   - Define global CSS variables for the main color of the icon and text, for example:

```
:root {
  --logo-icon-fill: #3b82f6; /* blue by default */
  --logo-text-fill: #ffffff; /* white by default */
}
```

   - Write styles for these classes in CSS using the variables:

```
.logo-icon {
  fill: var(--logo-icon-fill);
}
.logo-text {
  fill: var(--logo-text-fill);
}
```

   - If necessary, you can easily change the theme by redefining the variables, for example:

```
.winter-theme {
  --logo-icon-fill: #4ad3ff;
  --logo-text-fill: #e0f2fe;
}
```

4. **Check that the logo displays correctly in all browsers and does not lose its colors on responsive designs.** Scaling and maintaining proportions must be correct (you can use `width` and `height` in CSS for the logo container).

📌 What NOT to Do:

- Do not insert the logo via `<img src="logo.svg">` — this will not allow you to control colors via CSS.
- Do not leave hardcoded colors inside the SVG (e.g., `fill="#000000"`). All colors must be set via classes and CSS.

🧩 Source Files:

- Folder `/static/brand/logo.svg` — current logo file.
- File `/static/css/logo.css` — old styles for the logo (can be deleted or adapted to the new scheme).
- Page templates (`index.html`, `dashboard.html`, `stock-analysis.html`, `trading-journal.html`) — currently, the logo is connected via `#pp-logo`. This code needs to be replaced with inline-SVG.
